Abstract. Long non-coding RNAs (lncRNAs) have been reported to participate in multiple biological processes, including tumorigenesis. In the current study, the function of a novel lncRNA LINC00887 was investigated in lung carcinoma. For this purpose, LINC00887 expression was assessed by reverse-transcription quantitative PCR. Cell viability was determined by the CCK-8 and EdU assays. Cell invasion, migration were assessed by the transwell and wound healing assays, respectively. A dual luciferase assay was used for analysis of the interaction between LINC00887 and miR-206, as well as the relationship of miR-206 with NRP1. A tumor xenograft study was performed to investigate the LINC00887-miR-206-NRP1 axis in vivo. The expression levels of LINC00887 were upregulated in lung carcinoma tissues and cells compared with adjacent tissues or normal cells (BEAS-2B). Knockdown LINC00887 significantly inhibited the proliferation, migration and invasion of lung carcinoma cells (A549 and NCI-H460 cells). Furthermore, LINC00887 was identified as a competing endogenous RNA and to directly interact with miR-206. Mechanistically, miR-206 was demonstrated to regulate neuropilin-1 (NRP1) expression by targeting the NRP1 3'-untranslated region. The results of the present study suggested that the LINC00887-miR-206-NRP1 axis served a critical role in regulating lung carcinoma cell proliferation, migration and invasion. In addition, xenograft tumor model experiments revealed that silencing LINC00887 suppressed lung carcinoma tumor growth of in vivo. In summary, our results suggest that LINC00887 may serve an oncogenic role in lung carcinoma by targeting the miR-206/NRP1 axis, providing a potential therapeutic target for patients with lung carcinoma.

Introduction

Lung carcinoma is one of the most common types of cancer and one of the leading causes of cancer-associated deaths worldwide (1,2). In 2018, there were 2.1 million new cases and 1.8 million people died of lung cancer (3). The development and progression of lung cancer is a complicated process that may be associated with pleurisy or severe lung infections with bacteria and viruses or fungi, making lung cancer difficult to treat (4-6). Lung cancer can be divided into two categories, including non-small cell lung cancer (NSCLC) and small cell lung cancer (7). Although the treatment outcome for lung carcinoma have greatly improved due to advances in the technologies and treatment strategies, the prognosis of patients with lung carcinoma remains poor, since most patients are diagnosed at a late stage (8,9). Alternative natural therapies, such as β-himachalene, apigenin, geranial and Dracocephalum kotschyi, have demonstrated anticancer properties, but with disadvantages such as cytotoxic effects (10-14). Therefore, research has focused on the understanding of the molecular mechanisms of lung carcinoma and identifying novel diagnostic biomarkers and therapeutic targets.

Epigenetic modifications by long non-coding RNAs (lncRNAs) and microRNAs (miRNAs) are crucial for the development and metastasis of lung cancer (15). lncRNAs are a group of RNAs >200 nucleotides in length involved in multiple biological processes including gene imprinting, histone modification, chromatin remodeling, transcriptional activation, transcriptional interference, nuclear transport, and cell cycle regulation. IncRNAs are also involved in development of various types of tumor (16-18). For example, NEAT1 (non-coding nuclear enriched abundant transcript 1) is upregulated in breast cancer, colorectal cancer and non-small cell lung cancer (19,20). Small nucleolar RNA host gene 7 is upregulated in lung cancer tissues and cells and promotes the proliferation, migration and invasion of lung cancer cells by regulating Fas apoptotic inhibitory molecule 2 expression (21). miRNAs are a group of small non-coding RNAs that post-transcriptionally regulate gene expression and are also involved in tumor development and metastasis (22). Notably, lncRNAs have been reported to exert their functions as competing endogenous RNAs (ceRNAs) by sponging miRNAs (23-25). Previous studies have revealed various
IncRNA-miRNA-mRNA interaction networks in lung carcinoma (26-28). Cong et al (26) have demonstrated that IncRNA LINC00665 functions as a ceRNA to sponge miR-98, which regulates ERK signaling, and promotes the development of lung cancer. IncRNA PVT1 has been reported to competitively bind miR-424-5p, which is involved in regulating the coactivator-associated arginine methyltransferase 1 in NSCLC (29). Furthermore, IncRNAs can exert oncogenic roles, as well as function as tumor inhibitors. For example, IncRNA GACAT3 expression is decreased in NSCLC, and high expression levels of IncRNA GACAT3 inhibit the invasion and metastasis of NSCLC (30). Another study has demonstrated that IncRNA BX357664 suppresses NSCLC development by inhibiting cell proliferation and invasion (31). However, the roles of IncRNA-miRNA-mRNA networks in lung carcinoma remain unclear. Previously, LINC00887 has been identified to accelerate the malignant transformation ability of NSCLC cells (32). Using high-throughput nascent RNA capture sequencing, another study has identified LINC00887 as a highly expressed IncRNA in lung adenocarcinoma and squamous cell carcinoma (33). However, the detailed underlying mechanisms require further clarification.

The present study aimed to investigate the role of the LINC00887/miR-206/NRP1 axis in the development of lung cancer. LINC00887 functioned as the sponge of miR-206 to upregulate NRP1 expression. A decrease in LINC00887 may serve as a prognostic and diagnostic marker and also be used as a novel therapeutic target for patients with lung cancer.

Materials and methods

Clinical specimens. Lung carcinoma tissues and adjacent normal tissues (>5 cm from tumor) were obtained from 40 patients (age range, 35-70 years; mean age, 63±7.83 years) with lung cancer who underwent surgical resection at Shaanxi Provincial People’s Hospital (Xi’an, China) between March 2017 and December 2018. Two pathologists evaluated all specimens according to the World Health Organization guidelines and the pTNM Union for International Cancer Control pathological staging criteria (34). Inclusion criteria were: i) Primary lung cancer diagnosed by pathological examination; and ii) No local or systemic treatments were administered before surgery. All tissues were frozen in liquid nitrogen until RNA isolation. Written consent was obtained from all patients. The present study was approved by the Ethics Committee of Shaanxi Provincial People’s Hospital (approval number, XJYYLL-2019287).

Cell culture and transfection. Three lung carcinoma cell lines, namely the adenocarcinoma A549 cell line and the large cell carcinoma NCI-H1299 and NCI-H460 cell lines, were obtained from the American Type Culture Collection. The normal human bronchial epithelial BEAS-2B cell line was obtained from the Chinese Cell Bank of the Chinese Academy of Sciences. The cells were cultured in RPMI-1640 medium (Gibco; Thermo Fisher Scientific Inc.) with 10% FBS (Hyclone; GE Healthcare Life Sciences), 1% penicillin and streptomycin at 37°C with 5% CO2. Mycoplasma detection was negative in all cell lines.

BEAS-2B, A549 or NCI-H460 cells were seeded in 6- or 96-well plates. When the confluency reached 60-70%, the medium was changed to serum-free RPMI-1640, and transfection with small interfering (si)RNAs targeting LINC00887 or a control siRNA (si-Con). MiR-206 mimics, miR-206 inhibitors and their negative controls were obtained from Guangzhou RiboBio Co., Ltd. LINC00887 was overexpressed using the expression plasmid pcDNA3.1(+) (Invitrogen; Thermo Fisher Scientific Inc.). Empty vectors without LINC00887 cDNA were used as negative controls. LINC00887 siRNA (si-LINC00887, and negative control (si-NC) were purchased from Shanghai GenePharma Co. Ltd. Cells were transfected with LINC00887 siRNA, miR-206 mimics, miR-206 inhibitors and their negative controls at 50 nM concentration. All transfections were performed using Lipofectamine® 3000 (Invitrogen; Thermo Fisher Scientific, Inc.) according to the manufacturer's protocol. The sequences of all mimics and inhibitors and their negative controls are presented in the Table I. Cells were harvested 72 h after transfection for further experiments.

Reverse transcription-quantitative PCR (RT-qPCR). Total RNA from tissues and cell lines was isolated using TRIZol® reagent (Invitrogen; Thermo Fisher Scientific, Inc.). cDNA was synthesized using the PrimeScript RT reagent kit (Takara Bio, Inc.). qPCR was performed from cDNA using the SYBR® Green PrimeScript™ PLUS RT-qPCR kit (Takara Bio, Inc.). The reaction conditions were 95°C for 30 sec, 60°C for 40 sec (40 cycles), and a final extension step at 72°C for 10 min. Small RNA-rich samples were isolated from cells using TRIZol® reagent or the mirVana miRNA Isolation kit (Thermo Fisher Scientific, Inc.). U6 or GAPDH was used as an endogenous control. The relative expression levels were analyzed using the 2-ΔΔCq method (35). The primers used are listed in Table II.

Cell proliferation assays. A549 or NCI-H460 cells (3x10^3 cells/well) were seeded in 96-well plates. After transfection with si-NC or si-LINC00887, cell proliferation was evaluated using a Cell Counting Kit-8 (CCK-8) assay (Dojindo Molecular Technologies, Inc.) according to the manufacturer’s instructions. Cells were cultured for 0, 24,
48 or 96 h at 37˚C and incubated with 10 µl CCK-8 reagent per well at 37˚C for 1 h. The absorbance was measured at 450 nm using an Exl 800 microplate reader (BioTek China). The 5-ethyl-2'-deoxyuridine (EdU) staining assay was performed to determine DNA synthesis in proliferating cells using an EdU assay kit (Invitrogen; Thermo Fisher Scientific, Inc.). After transfection with si-NC or si-LINC00887, A549 or NCI-H460 cells were cultured at 37˚C for 48 h, fixed with 4% paraformaldehyde at room temperature for 10 min and permeabilized with 0.3% Triton X-100 at room temperature for 10 min. Subsequently, cells were incubated with 10 µM EdU for 2 h at 37˚C, and cell nuclei were stained with DAPI (5 µg/ml) at room temperature for 10 min. The number of EdU-positive cells was counted under a light microscope in five random fields (magnification, x100; Olympus Corporation). All assays were independently performed in triplicate.

Wound healing assay. After transfection with si-NC or si-LINC00887, A549 or NCI-H460 cells (4x10^4 cells/well) were seeded in 6-well plates and cultured at 37˚C until confluent. The wound was created by scratching the cell layer with a sterile pipette tip. The floating cells were washed away using PBS. The streaked cells were cultured in serum-free RPMI-640 medium at 37˚C for 48 h. An inverted optical microscope (Olympus Corporation) was used to monitor the closure of the wound at 0 and 48 h at x50 magnification. The gap distance was quantitatively evaluated using ImageJ software (version 1.49; National Institutes of Health).

Cell migration and invasion assays. For invasion assays, 24-well Transwell chambers (8.0 µm pore size, Costar; Corning, Inc.) with Matrigel-precoated membranes were used. A total of 1x10^5 A549 or NCI-H460 cells in 100 µl FBS-free RPMI-1640 were added to the upper chambers, while 500 µl RPMI-1640 medium with 10% FBS was added to the bottom chambers. After 48 h, the non-invaded cells on the upper side of the membrane in the chamber were removed by swabs, and the invading cells in the lower side of the chamber were stained with 0.1% crystal violet for 20 min at room temperature. The cells were observed and counted under a light microscope (magnification, x200; Olympus Corporation). For migration detection, the Matrigel was not used and all other steps were the same as the cell invasion assay.

Western blotting. A549 or NCI-H460 cells were lysed using RIPA buffer (Sigma-Aldrich; Merck KGaA) with 1 mM phenylmethylsulphonyl fluoride. The concentration of obtained total protein was quantified using a BCA protein assay kit (Thermo Fisher Scientific, Inc.). Equal amounts (25 µg) of proteins were loaded and separated via 10% SDS-PAGE and electro-transferred to a PVDF membrane (EMD Millipore). After blocking with 5% bovine serum albumin (Beyotime Institute of Biotechnology) at room temperature for 1 h, the membrane was incubated with anti-neuropilin 1 (NRP1) (1:2,000; cat. no. ab81321; Abcam) and anti-β-actin (1:5,000; ab179467; Abcam) primary antibodies at 4˚C overnight. After washing three times with TBST (5 min per wash), the members were subsequently incubated with an HRP-labelled goat anti-rabbit secondary antibody (ab6721; 1:10,000; Abcam) at room temperature for 1 h. The immunolabelling was visualized using an ECL system (EMD Millipore) according to the manufacturer's protocol. All assays were performed independently in triplicate and the densitometric analysis was performed using ImageJ (version 1.49; National Institutes of Health).

Dual-luciferase reporter assay. The reporter plasmid containing 3’UTR of LINC00887 or NRP1 with wild (Wt LINC00887 or Wt NRP1) or mutant (Mut LINC00887 or Mut NRP1) miR-206 binding sites were constructed by Guangzhou Ribobio Co. Ltd. For the reporter assay, lung cancer cells or 293T cells in 24-well plates and co-transfected with the reporter plasmid and miR-206 mimic or NC using Lipofectamine 2000 (Invitrogen, Thermo Fisher Scientific, Inc.). Cells were harvested 48 h later and assayed with a luciferase reporter assay system (Promega Corporation). The relative luciferase activity was normalized to Renilla luciferase activity.

Tumor xenograft model. BALB/c nude mice (age, 8 weeks; weight, 21-25 g) were obtained from Beijing Vital River Laboratory Animal Technology Co., Ltd., and housed at a room temperature of 25˚C with a 12 h light/dark cycle. The mice were maintained in an individually ventilated cage system under specific pathogen-free conditions (temperature; 25˚C; humidity, 55%) with free access to food and water. Then the posterior flank of 6-week-old male BALB/c nude mice (n=10) were subcutaneously injected with NCI-H460 (4x10^6) cells transfected with si-NRP1 or si-negative control (NC). Tumor volumes were examined every 4 days. After 17 days, the mice were euthanized by CO₂ inhalation (CO₂ flow rate, 20% of cage volume) and tumor tissues were dissected, photographed and weighed. The expression levels of miR-206 in tumor tissues were independently performed in triplicate.

NRP1, neuropilin 1; miR, microRNA.
were detected by RT-qPCR as aforementioned. The protein levels of NRPI in tumor tissues were measured by western blotting as aforementioned. The murine experiments were conducted in July 2017. The animal experiment was performed in compliance with the authenticated animal protocols of the Ethical Committee of Animal Welfare of Shaanxi Provincial People's Hospital (approval No. IACUC-20190116).

Target prediction. Potential target miRNAs of LINC00887 were predicted using LncBase V2 (http://carolina.imis.athena-innovation.gr/diana_tools/web/index.php?r=Lncbasev2/index). The target genes of miR-206 were predicted using the bioinformatics algorithms: TargetScanV7.2 (http://www.targetscan.org/vert_72/).

Statistical analysis. Statistical analyses were performed using GraphPad Prism 7.0 (GraphPad Software, Inc.). Data are presented as the mean ± SD for three independent experiments. The differences between two groups were analyzed by unpaired Student's t-test, and one-way ANOVA followed by the Tukey's post hoc test was performed to analyze the differences among more than 2 groups. Pearson's correlation analysis was performed to analyze the correlation between LINC00887 and miR-206 expression as well as the clinical variables. P<0.05 was considered to indicate a statistically significant difference.

Results

LINC00887 is upregulated in lung carcinoma tissues and cell lines. RT-qPCR was performed to analyze the expression levels of LINC00887 in the collected 40 pairs of lung carcinoma and adjacent normal tissues. As presented in Fig. 1A, LINC00887 expression levels were significantly upregulated in lung carcinoma tissues compared with those in adjacent normal tissues (P<0.001). To assess the association of LINC00887 expression with clinicopathologic characteristics, the expression levels of LINC00887 were categorized as low (n=20) or high (n=20) in relation to the median value (cut-off, 2.12). High LINC00887 expression was significantly associated with advanced TNM stage and lymph node metastasis (Table III). Additionally, LINC00887 expression levels were significantly higher in three lung cancer cell lines (NCI-H460, A549 and NCI-H1299) compared with those in the normal human bronchial epithelium BEAS-2B cell line (Fig. 1B). NCI-H460 and A549, which exhibited high expression levels of LINC00887, were used for subsequent in vitro assays.

LINC00887 knockdown suppresses proliferation, migration and invasion of lung carcinoma cells in vitro. To investigate the function of LINC00887, the expression of LINC00887 was knocked down using siRNAs. All three siRNAs mentioned in Table I significantly silenced LINC00887 expression compared with that in the si-Con group, with si-LINC00887-2 exhibiting the strongest knockdown efficiency (Fig. 2A). Therefore, subsequent experiments were performed using si-LINC00887-2. The CCK-8 assay demonstrated that cell proliferation was significantly decreased in A549 and NCI-H460 lung carcinoma cells after si-LINC00887 transfection compared with that in cells transfected with si-Con (P<0.01; Fig. 2B and C).
Consistently, EdU and DAPI double staining confirmed that LINC00887 knockdown significantly inhibited the proliferation of A549 and NCI-H460 cells (P<0.05; Figs. 2D and S1). Furthermore, Transwell assays revealed that silencing LINC00887 significantly inhibited the migratory and invasive capabilities of A549 and NCI-H460 lung carcinoma cells (P<0.01; Fig. 2E-G). In addition, wound healing assays demonstrated that LINC00887 knockdown significantly decreased the relative wound closure in A549 and NCI-H460 cells (P<0.01; Fig. 2H and I). To further...
validate the function of LINC00887, LINC00887 was overexpressed in normal human lung epithelial BEAS-2B cells (Fig. S2A). LINC00887 overexpression did not alter cell proliferation, migration and invasion in normal BEAS-2B cells (Fig. S2B-F). In summary, the present results suggested that LINC00887 knockdown suppressed the proliferation, migration and invasion of lung carcinoma cells in vitro.

**LINC00887 directly interacts with miR-206.** Multiple studies have demonstrated that lncRNAs can exert their functions as competing endogenous RNAs (ceRNAs) by competitively binding miRNAs involved in regulating target gene expression (36,37). However, whether LINC00887 has a similar function in lung carcinoma remains unknown. Using the bioinformatics DIANA tool Incbase V2 (38), miR-206 was identified to have putative binding sites with LINC00887 (Fig. 3A). To verify whether LINC00887 directly interacted with miR-206, Dual-Luciferase reporter assays were performed, and the results revealed that the miR-206 mimic significantly inhibited the luciferase activity of the LINC00887-wt reporter, but not that of the LINC00887-mut reporter (Fig. 3B). In addition, the regulation between miR-206 and LINC00887 was further examined; as presented in Fig. 3C, LINC00887 knockdown significantly upregulated miR-206 expression, whereas miR-206 overexpression using the miR-206 mimic significantly downregulated LINC00887 expression in A549 and NCI-H460 lung carcinoma cells (Fig. 3D). Notably, significantly lower levels of miR-206 were detected in lung carcinoma tissues compared with those in adjacent normal tissues (Fig. 3E). Pearson's correlation analysis revealed that miR-206 expression was negatively correlated with LINC00887 expression (P<0.001; Fig. 3F).

**LINC00887 regulates lung carcinoma cell proliferation, migration and invasion via miR-206.** To further investigate the functional association between LINC00887 and miR-206, and test whether LINC00887 exerts its function via miR-206, a miR-206 inhibitor was used to downregulate miR-206 expression in lung carcinoma A549 and NCI-H460 cells (Fig. 4A). As LINC00887 knockdown enhanced miR-206 expression (Fig. 3C), A549 and NCI-H460 cells transfected with si-LINC00887 were further transfected with the miR-206 inhibitor or inhibitor-NC. As presented in Figs. 4B-D and S3,
Figure 4. Continued.
the results of the CCK-8 and EdU/DAPI staining assays demonstrated that LINC00887 knockdown significantly inhibited cell proliferation, whereas miR-206 inhibitor ameliorated the inhibition of cell proliferation induced by LINC00887 knockdown in lung carcinoma A549 and NCI-H460 cells. Consistently, as demonstrated by Transwell and wound healing assays, silencing LINC00887 significantly inhibited cell migration or invasion, whereas miR-206 inhibitor ameliorated the inhibition of cell migration or invasion induced by LINC00887 knockdown in lung carcinoma A549 and NCI-H460 cells (Fig. 4E-I).

miR-206 regulates NRPI expression by targeting NRPI 3'-UTR. To determine the target of miR-206 in lung carcinoma, bioinformatics prediction was performed using TargetScan, which revealed that miR-206 targeted the 3'-UTR of NRPI with 17 complementary binding sites (Fig. 5A). To validate the prediction, Dual-Luciferase reporter assay was performed, and the results demonstrated that the relative luciferase activities in 293T cells transfected with the NRPI-wt reporter vector, but not with NRPI-mut, were inhibited by co-transfection with the miR-206 mimic (Fig. 5B). Furthermore, miR-206

Figure 4. LINC00887 regulates lung carcinoma cell proliferation, migration and invasion via miR-206. (A) Expression levels of miR-206 in lung carcinoma A549 and NCI-H460 cells transfected with inhibitor-NC or miR-206 inhibitor were examined by reverse transcription-quantitative PCR. (B and C) Lung carcinoma A549 or NCI-H460 cells were co-transfected with si-LINC00887 and inhibitor-NC or miR-206 inhibitor. (B and C) Cell proliferation was analyzed using the Cell Counting Kit-8 assay in (B) A549 and (C) NCI-H460 cells at the indicated time points. (D) Cell proliferation was analyzed by EdU and DAPI staining 72 h post transfection. (E) Transwell assays were used to analyze (F) cell migration and (G) invasion. Scale bar, 200 µm. (H and I) Relative wound closure was examined by wound healing assay. Scale bar, 200 µm. Data are presented as the mean ± SD. *P<0.05; **P<0.01 vs. NC. overexpression significantly downregulated both the mRNA and protein levels of NRP1 in lung carcinoma A549 and NCI-H460 cells (Figs. 5C, E and F, and S5). In addition, significantly higher expression levels of NRP1 were detected in lung carcinoma tissues compared with those in the adjacent normal control tissues (Fig. 5D).

**LINC00887-miR-206-NRP1 interaction network regulates lung carcinoma cell proliferation, migration and invasion.** To further validate the functionality of the LINC00887-miR-206-NRP1 interaction network, lung carcinoma A549 and NCI-H460 cells were transfected with si-LINC00887, miR-206 mimic, si-NRP1 or the si-NC. CCK-8 assays revealed that compared with the NC, transfection with si-LINC00887, miR-206 mimic or si-NRP1 significantly inhibited A549 and NCI-H460 cell proliferation (Figs. 6A and B, and S5). The effect of si-LINC00887, miR-206 mimic on cell proliferation was further confirmed using EdU/DAPI staining (Figs. 6C and S4). Transwell assays demonstrated that LINC00887 knockdown, miR-206 overexpression or NRP1 silencing significantly inhibited migration and invasion of A549 and NCI-H460 cells (Fig. 6D-F). In addition, wound healing assays revealed that si-LINC00887, miR-206 mimic significantly inhibited the relative migration distance of A549 and NCI-H460 (Fig. 6G and H). NRP1 protein levels in A549 and NCI-H460 cells transfected with miR-NC or miR-206 mimic were further analyzed. Compared with the NC group, LINC00887 knockdown, miR-206 overexpression or NRP1 silencing significantly inhibited NRP1 protein expression, with si-NRP1 transfection exhibiting the lowest expression levels of NRP1 protein among all groups (Fig. 6I and J).

**LINC00887 knockdown inhibits lung carcinoma tumor growth in vivo.** To investigate the function of LINC00887 on tumor growth in vivo, a xenograft tumor model was established using NCI-H460 cells transfected with si-NC or si-LINC00887 (Fig. 7A). The tumor volume was measured every 4 days after implantation and mice were euthanized on day 17 (Fig. 7B). Compared with the NC group, the tumor growth was significantly inhibited in the si-LINC00887 group (Fig. 7B), with significantly lower xenograft tumor sizes and weights (Fig. 7A-D). Additionally, LINC00887
XU et al: LINC00887 REGULATES miR-206/NRP1 IN LUNG CARCINOMA

Figure 6. Continued.
and miR-206 expression in tumor tissues were examined. As presented in Fig. 7E and F, tumor tissues from the mice in the si-LINC00887 group exhibited significantly lower expression levels of LINC00887 and significantly higher expression levels of miR-206 compared with those in tissues from mice in the si-NC group. NRP1 protein levels were significantly downregulated in tumor tissues from the si-LINC00887 group compared with those in tissues from the si-NC group (Fig. 7G and H). Overall, these results suggested that LINC00887 knockdown suppressed lung carcinoma growth in a xenograft model.

**Discussion**

Emerging studies have demonstrated that IncRNAs are important regulators that act as oncogenic or tumor suppressor molecules in various tumors (17,39). For example, the metastasis-associated lung adenocarcinoma transcript 1 (MALAT1), also called NEAT2, is an abundant and highly conserved IncRNA across vertebrates. MALAT1 induces an EMT switch via the PI3K/AKT pathway in epithelial ovarian cancer (40). Moreover, MALAT1 expression has been reported to be a potential predictor of tumor
metastasis and prognosis in CRC (41). Maternally expressed 3 was considered as a tumor suppressor and a potential therapeutic candidate in cervical tumors (42). IncRNAs exert their functions by sponging miRNAs via lncRNA-miRNA-mRNA regulatory axes (23-25). The present study extended the understanding of the lncRNA-miRNA-mRNA networks by revealing that LINC00887 directly interacted with miR-206, whereas miR-206 targeted NRP1 to promote the progression of lung carcinoma.

LINC00887 is a newly identified lncRNA involved in multiple types of cancer. Low LINC00887 expression levels have been observed in an invasive follicular thyroid carcinoma (43). A microarray analysis conducted by Zhu et al (44) has revealed that LINC00887 is one of the top 10 downregulated lncRNAs between stage II and stage III colorectal cancer. In human papillary thyroid cancer, a previous study has demonstrated that the expression levels of LINC00887 are upregulated compared with those in non-tumor thyroid tissues (45). Therefore, LINC00887 may function as an oncogenic lncRNA or a tumor suppressor in different types of tumors. In the present study, the expression levels of LINC00887 were upregulated in lung carcinoma tissues and cells compared with those in healthy tissues and cells; therefore, LINC00887 may act as an oncogene in lung cancer. Consistently, LINC00887 knockdown suppressed lung carcinoma cell proliferation, migration and invasion in vitro, as well as lung xenograft tumor growth in vivo.

Multiple miRNAs have been predicted as the potential targets of LINC00887, such as miR-138, miR-181 and miR-204 (45). In the present study, LINC00887 was identified to directly interact with miR-206. miR-206 has been reported as a tumor suppressor inhibiting cell proliferation, migration and invasion in gastric, colorectal, breast and laryngeal cancer (46-49). Furthermore, Samaeeia et al (50) have reported that miR-206 inhibits stemness and metastasis of breast cancer by regulating the myocardin-related transcription factor A/interleukin-11 signaling pathway. In the present study, the expression levels of miR-206 were downregulated in lung carcinoma tissues compared with those in healthy tissues, suggesting that it may be a tumor suppressor. Additionally, miR-206 overexpression inhibited lung carcinoma A549 or NCI-H460 cell proliferation, migration and invasion.

In the present study, NRP1 was identified as a direct target gene controlled by miR-206. NRP1 is a transmembrane glycoprotein that acts as a co-receptor for vascular endothelial growth factor and transforming growth factor-β, and is a promising novel target for chronic lymphocytic leukaemia therapy (51). NRP1 has been reported to be regulated by multiple miRNAs, such as miR-130, miR-141 and miR-338 in ovarian cancer, gastric cancer and pancreatic cancer (52-54). Additionally, a previous study has demonstrated that miR-206 regulates NRP1 expression in breast cancer (55). Consistently, the present study revealed that miR-206 regulated NRP1 expression by targeting the NRP1 3'-UTR in lung carcinoma cells. However, future studies are required to determine whether miR-206 has other targets and whether NRP1 is also regulated by multiple miRNAs in lung carcinoma. Bioinformatics analysis should be performed to analyze the association between the expression levels of LINC00887 and miR-206/NRP1 in patients with lung cancer in The Cancer Genome Atlas database.
In conclusion, the results of the present study revealed that LINC00887 was upregulated in lung carcinoma tissues and cell lines. Furthermore, LINC00887 promoted lung carcinoma progression and metastasis by sponging miR-206 to regulate NR1P1 expression. The xenograft tumor model experiment demonstrated that LINC00887 knockdown inhibited lung tumor growth in vivo. Overall, the LINC00887-miR-206-NR1P1 axis may reveal a novel insight for lung tumorigenesis and may provide potential therapeutic strategies for patients with lung carcinoma.

Acknowledgements

Not applicable.

Funding

No funding was received.

Availability of data and materials

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Authors' contributions

LBX and XPR conceived and designed the experiments. BXB, JX and YJR performed the experiments. DH and SHW analyzed and interpreted the data. LBX wrote the manuscript. XPR revised the manuscript. All the authors read and approved the final manuscript.

Ethics approval and consent to participate

Written informed consent was obtained from all patients. The present study was approved by the Ethics Committee of Shaanxi Provincial People's Hospital. The present study was approved by the Ethics Committee of Shaanxi Provincial People's Hospital.

Patient consent for publication

Not applicable.

Competing interests

The authors declare that they have no competing interests.
